Problems 127

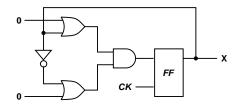

Figure 5.28: Circuit for Problem 5.10.

- 5.12 Reexamine the cases (a) and (b) of the previous problem for an input pulse of 1 unit width. Note that the gate filters out a pulse narrower than its own delay a phenomenon known as spike suppression.
- 5.13 Explain what action an event-driven true-value simulator will take when it evaluates a zero-delay gate.
- 5.14 For implementing an event-driven simulator for unit-delay simulation, what is the minimum number of time slots needed?
- 5.15 Suppose that the fault coverage increases linearly from 0 to 100% as a large number of vectors is applied. Show that a serial fault simulator will take about half the CPU time with fault dropping than without. Assume that in fault dropping any fault is dropped the first time it is detected.
- 5.16 Show that when n faults are simulated without fault dropping, a parallel fault simulator on a w-bit word computer will run (n+1)(w-1)/n times faster than a serial fault simulator.
- 5.17 Assuming a four-bit machine word, demonstrate parallel fault simulation of vector (1,0,1) for the three single stuck-at-1 faults on the second primary input and its two fanouts, respectively, in the circuit of Figure 5.22.
- 5.18 Derive the output fault list  $L_c$  for an exclusive-OR gate,  $c = a \oplus b$ , in terms of the input fault lists,  $L_a$  and  $L_b$ .
- 5.19 Explain why a concurrent fault simulator requires more memory than a deductive fault simulator.
- $5.20~{\rm A~VLSI}$  design center is equipped to design digital circuits with embedded memory blocks. The circuits are modeled at the logic level but the simulator must have a four-state (0,1,X,Z) signal representation. Only single stuck-at faults are to be simulated. In order to select a fault simulator, you must answer the following questions:
  - (a) Which of the simulators among serial, parallel, deductive, and concurrent, can simulate the circuits?
  - (b) Which is the best choice among these four simulators?
