Abstract: The paper describes basic concepts of neural networks and fuzzy systems. It is shows that most commonly used neural network architecture of MLP – Multi Layer Perceptron is also one of the least efficient ones. Also most commonly used EBP – Error Back Propagation algorithm is not only very slow, but also it is not able to find solutions for optimal neural network architectures. EBP can solve problems only when large number of neurons is used, but this way neural network loses its generalization property. Performances of both fuzzy systems and neural networks are compared leading to the conclusion that neural networks can produce much more accurate nonlinear mapping and they are simple to implement. At the end of the presentation several concepts of neuro-fuzzy systems are compared.

Keywords: Learning, neural networks, fuzzy systems, perceptron, neuro-fuzzy.

1 Introduction

Both neural networks and fuzzy systems perform nonlinear mapping and both systems internally operate within a limited signal range between zero and one. In general, all parameters of fuzzy systems are designed, while parameters of neural networks are being obtained by a training process. It is relatively easy for humans to follow the computation process of fuzzy systems, while it is almost impossible to do as in the case of neural networks. Neural networks can handle basically an unlimited number of inputs and outputs while fuzzy systems have one output and number of inputs is practically limited to 2 or 3. The resulted nonlinear function produced by neural networks is smooth while functions produced by fuzzy systems are relatively rough (see Fig. 1).

It is relative easy to design fuzzy systems based on a designer’s intuition. In case of neural networks a designer may face many challenges. The first challenge is that it is difficult to decide how many neurons to use and how they have to be connected. Second problem, which often leads to frustration, is how to train neural networks. As a result far from optimum neural network architectures are selected and learning algorithms which are not able to produce a good solution are used. These issues will be discussed in section 2 of this presentation. However, if difficulties with neural networks are solved then neural networks generate not only a better and smoother control surface, but also its microcontroller implementations requires shorter code and faster operation [1]. Of course it is possible to merge these two technologies by developing neuro-fuzzy systems.
2 Neural Networks

Artificial neural networks consist of many neurons with a sigmoid activation function as shown in Fig. 2. These neurons are connected in such a way that the feed forward signal flow is assured. Connecting weights may have both positive and negative values and the resulted neuron excitation $net$ is calculated as a sum of products of incoming signals multiplied by weights:

$$net = \sum_{i=1}^{n} w_i x_i$$

$$out = f(net) = \frac{1}{1 + \exp(-knet)}$$

Fig. 2. Unipolar activation function of a neuron

2.1 Neural Network Architectures

The most commonly used architecture is MLP – Multi Layer Perceptron as shown in Fig. 3. The only advantage of MLP is that it is relatively easy to write software for this architecture. Unfortunately when using MLP topology more neurons are needed to solve problems. A better option is to use MLP with connections across layers. This architecture is not only more powerful but it can be trained faster, assuming that we have written a proper software. The most powerful architecture is the cascade architecture, also known as FCN – Fully Connected Network shown in Fig. 4.

Fig. 3. MLP - Multi Layer Perceptron architecture for neural networks

Fig. 4. FCN – Fully Connected Network or cascade network architecture

2.2 Neural Network Training

The most common training algorithm is EBP – Error Back Propagation [2]. It is relatively simple and it does not require a lot of computer resources. This algorithm however seldom leads to a good solution and is extremely slow. The EBP show some advantages for MLP networks [3][4]. Much better results can be obtained with the LM – Levenberg-Marquardt Algorithm [5]. Even better results can be obtained with NBN – Neuron by Neuron algorithm [6]. Note that in the LM algorithm an N by N matrix must be inverted in every iteration. This is the reason why for large size neural networks the LM algorithm is not practical. Also most of implementations of LM algorithms (like
popular MATLAB NN Toolbox) are developed only for MLP. The Neuron by Neuron (NBN) algorithm was developed in order to eliminate most disadvantages of the LM algorithm. Detailed descriptions of the algorithm can be found in [6][7].

Figures 5 through 7 shows results of training of MLP architecture for the Parity-4 problem. One may notice that EBP training requires 200 times more iterations and 100 times longer time to train. Also the success rate is smaller than in the case of other algorithms. LM algorithm is slightly faster but it has a smaller success rate in comparison to NBN algorithm. For the FCN architecture, with 3 neurons connected in cascade, the parity problem can be solved with significantly smaller number of neurons (3 instead of 7). Unfortunately EBP algorithm cannot solve this problem with less than 10,000 iterations. The standard LM algorithm is not suitable for FCN architecture; but NBN algorithm can solve this problem in a short time with the success rate of 98%. Training results for Parity-4 problem are summarized in Table I.

</tbody>
</table>

For MLP topologies it seems that the EBP algorithm is most robust and has the largest success rate for random weight initialization. At the same time the EBP algorithm requires over 200 times larger number of iterations to converge.

If the number of neurons in FCN is increased to 4 then also EBP algorithm can solve the problem with success rate of 98%. The NBN algorithm can solve this problem in 150 times shorter time with 100% success rate. Results are shown in Table II. One may also notice that with increasing of network complexity neural networks are losing their ability for generalization (if neural network is used for nonlinear mapping).

For experiments shown in Table III the LM algorithm was modified so not only MLP networks but all arbitrarily connected neural networks could be trained. Also in both LM and NBN algorithms the matrix inversion, the Gauss-Jordan method, was replaced by the LU decomposition. As a consequence the training time was significantly reduced.

One may notice that if too large neural networks are used the system can find solutions which produce very small error for the training patterns, but for patterns which were not used for training errors actually could be much larger than in the case of much simpler network.

What many people are not also aware of is that not all popular algorithms can train every neural network. Surprisingly, the most popular EBP (Error Back Propagation) algorithm cannot handle more complex problems while other more advanced...
algorithms can. Also, in most cases neural networks trained with popular algorithms such as EBP produce far from optimum solutions [3][4].

**Fuzzy Systems**

The fuzzy set system theory was developed by Zadeh [8]. Fuzzy logic is similar to Boolean algebra, but it operates on analog values between zero and one. Also, instead of AND and OR operators the MIN and MAX operators are used as is shown in Fig. 10.

Fig. 10. Comparison Boolean algebra with fuzzy logic.

In order to solve problem of nonlinear mapping two similar approaches are usually taken: Mamdani[9] and TSK[10][11]. Block diagrams for these two controllers are shown in Figures 11 and 12.

**Neuro-Fuzzy Systems**

Most commonly used neuro-fuzzy architecture is shown in Fig 13. It has neural network topology, but its operation does not resemble biological neuron operations. This concept of neuro-fuzzy architecture requires signal multiplication and division and as result it is not easy to implement this concept in hardware.

It is, however, possible to implement fuzzy systems using typical neurons with sigmoid activation functions. One such implementation may follow the the concept of counterpropagation neural networks[4]. Actually TSK fuzzy systems have a very similar topology. Unfortunately, the counterpropagation networks operate correctly only on normalized inputs. Normalization of inputs lead to removal of important information so it cannot be used. However, by increasing the dimensionality of input dimensionality it is possible to project input data on sphere (or hypersphere) without losing important information. The neuro-fuzzy system based on the counterpropagation network with input pattern transformation is shown in Fig. 14. In the network of Fig. each neuron is responsible for one fuzzy rule.

**Fig. 11.** Block diagram of a Mamdani type fuzzy controller

**Fig. 12.** TSK (Takagi-Sugeno-Kang) fuzzy architecture.

**Fig. 13.** Classical Neuro-Fuzzy Architecture.
Fig. 14. Fuzzy controller based on counterpropagation network

All neurons in Fig. 14 have a unipolar activation function and if the system is properly designed, then for any input vector in certain areas only the neuron of this area produces +1 while all remaining neurons have zero values. In the case of when the input vector is close to a boundary between two or more regions, then all participating neurons are producing fractional values and the system output is generated as a weighted sum. For proper operation it is important that the sum of all outputs of the second layer must be equal to +1. In order to assure the above condition, an additional normalization block can be introduced, in a similar way as it is done in TSK fuzzy systems as shown in Fig. 12.

Another concept of replacing fuzzy systems with neural networks is shown in Fig. 14 [12]. This network can be considered as a fuzzy system with sigmoid membership functions [12].

Comparison of neural networks and fuzzy systems

Fuzzy systems utilize the expert information in the form of a set of rules. There are several reasons for using fuzzy systems in control engineering practice. First, the dynamics of the system under interest is generally complicated, but sometimes its behavior can be defined more easily in linguistic terms. Second, fuzzy systems are suitable architectures for modification and tuning process, which provides some kind of adaptiveness through the on-line adjustment of parameters. The major advantage of fuzzy logic based systems is their ability to utilize expert knowledge and perception based information.

Artificial neural networks are well known by their property of performing complex nonlinear mappings. Earlier works on the mapping properties of these architectures have shown that neural networks are universal approximators [13,14].

Fig. 15. Required control function and a comparison of the results obtained with microcontroller implementation using fuzzy and neural systems
Fig. 16. Control surfaces obtained with Motorola microcontroller HC11 using fuzzy approach with trapezoidal membership functions (7 functions per input) and TSK defuzzification [1].

Fig. 17. Control surfaces obtained with Motorola microcontroller HC11 using fuzzy approach with six neurons 2-1-1-1-1-1 architecture and Elliot activation function. [1]

Figures 15 to 17 show a comparison of fuzzy and neural networks based system implemented in Motorola HC11 microcontroller. Motorola’s 68HC711E9 is a low cost, 8-bit microprocessor; the on-board features of which are 512 bytes of RAM and EEPROM and 12K bytes of UV erasable EPROM. The processor was used with an 8 MHz crystal, allowing an internal clock frequency of 2 MHz.

Currently, fuzzy controllers are the most popular choice for hardware implementation of complex control surfaces because they are easy to design. Neural controllers are more complex and harder to train, but provide an outstanding control surface with much less error than that of a fuzzy controller.

A drawback of neural controllers is that the design process is more complicated than that of fuzzy controllers. However, this difficulty can be easily overcome with proper design tools. One severe disadvantage of a fuzzy system is its limited ability of handling problems with multiple inputs. In the case of neural networks such a limitation does not exist. Furthermore, control surfaces obtained from neural controllers also do not exhibit the roughness of fuzzy controllers that can lead to unstable or rough control.

Both neural networks and fuzzy systems are capable of approximating any nonlinear function, but their implementation in silicon is not easy. Both neural and fuzzy systems have their advantages and limitations.

One may notice that TSK fuzzy controller can be easily replaced by neural network with very simple architecture. In this case the intuitive fuzzy rules can be used as patterns to train neural networks. This approach is not only very simple but it also produces a smooth control surface. In most cases these neural networks which are replacing fuzzy systems require hardware.

Conclusion

The paper describes basic concepts of neural networks and fuzzy systems. It is shown that most commonly used neural network architecture of MLP – Multi Layer Perceptron is also one of the least efficient ones. Also most commonly used EBP – Error Back Propagation algorithm is not only very slow, but also it is not able to find solutions for optimal neural network architectures. EBP can solve problems only when large number of neurons is used, but this way neural network loses its generalization property. Performances of both fuzzy systems and neural networks are compared leading to the conclusion that neural networks can produce much more accurate nonlinear mapping that are simple to implement. At the end of the presentation several concepts of neuro-fuzzy systems are compared.

VIII. CONCLUSION

Neural networks exhibit superior performance in comparison to fuzzy systems but there are several reasons for frustration of people trying to adapt neural networks for their research:

- Neural networks can be over-trained if excessive number of neurons are used. This way the network is losing its ability for generalization and it is not able to correctly process new patterns which were not used for training.
- In most cases the relatively inefficient MLP architecture is used instead of more powerful topologies with connections across layers. As a result, full power of neural networks is not utilized.
- In order to find solutions for close to optimal architectures, second order algorithms such as NBN or LM should be used. Unfortunately, the LM algorithm adopted in popular MATLAB NN Toolbox can handle only MLP topology without connections across layers and these topologies are far from optimal.
- Newly developed NBN algorithm is very fast, it can train any neural network architectures and it has no limitations for the number of patterns used in training. Additional feature of this algorithm is that individual patterns can be added or subtracted from the training set without necessity of training network with entire set of patterns.

The only current limitation of the NBN algorithm is that neural networks should not be too big and practically it can train networks with up to 500 weights.
