

Due: Monday, February 06, 2012 by 11:59 PM

Deliverables:

The following project file must be submitted to the “graded” assignment by the due date and time specified above (see the Lab Guidelines for information on submitting project files). You should plan to start on the project not later than Wednesday in lab. To ensure that your classes and methods are named correctly, you should make sure that your file is successfully submitted to the “ungraded” assignment in Web-CAT during lab on Wednesday. **Projects sent via e-mail past the deadline at 11:59 PM will not be accepted without a university-approved excuse.**

Files to submit to Web-CAT:

- UsernameGenerator.java

Directions:

UsernameGenerator.java

- **Requirements:** Create a program that prompts for and reads the user’s first and last name separately. The program should then print a string composed of (1) the first letter of the user’s first name, (2) followed by the third letter of the user’s first name, (3) followed by the first letter of the user’s last name, (4) followed by a random number in the range 100 to 999. Notes: (a) For #2 above, if the user’s first name has less than three letters, you should use the last letter of the user’s first name; (b) the printed username should be in all lower case. Similar algorithms are sometimes used to generate usernames for new user. After the username is generated, the program should prompt the user to **set up** and **confirm** a password, which should be of type String. If the user fails to confirm the password, the program should print an appropriate message that contains the word “failed” as shown in Scenario 2 below.
- **Design:** Your program will need to accept all values as type String. Your program output should be **exactly** as follows (replace everything in italics with your own words):

Scenario 1: if the passwords user types in match.

Line #	Program output
1	<i>Prompt the user’s first name:</i>
2	<i>Patty</i>
3	<i>Prompt the user’s last name:</i>
4	<i>Liu</i>
5	<i>Prompt user for password:</i>
6	<i>Y234U</i>
7	<i>Prompt user to type in the password again:</i>
8	<i>Y234U</i>
9	
10	Welcome Patty Liu!
11	Your username is ptl389
12	Your password is Y234U

Scenario 2: if the passwords user types in don't match.

Line #	Program output
1	<i>Prompt the user's first name:</i>
2	<i>Patty</i>
3	<i>Prompt the user's last name:</i>
4	<i>Liu</i>
5	<i>Prompt user for password:</i>
6	<i>Y234U</i>
7	<i>Prompt user to type in the password again:</i>
8	<i>Y234Y</i>
9	
10	Failed to set up the new user's login information.
11	

- **Code:** Your program should use the `nextLine` method of the `Scanner` class to read user input. Note that this method returns the input as a `String`. See the `String` class in the Java API for details on methods such as: `length`, `charAt`, `toLowerCase`, `equals`, `substring`, etc. You have two choices for generating random numbers: the `Math.random` method and (2) the `java.util.Random` class which has methods for returning a random numbers. See the Java API documentation (`Math` class and the `Random` class) for details. Section 3.4 in the text has examples of using the `Random` class and its methods. With either approach, you'll need to think of a way to ensure that the random numbers are in the range of 100 to 999 (e.g., adding an offset).
- **Test:** You should test several users with different names. Make sure that the letter portion of the username generated from your program follows the requirements above and the numbers in the username are random numbers.
